7 The present application is the subject of Provisional
8 Application Serial No. 60/347,295 filed January 14, 2002

9 The present application is a continuation in part of US Patent
10 Application Serial Number 09/866,925 filed May 30, 2001 entitled
11 ALGORITHMIC DETERMINATION OF FLANKING DNA SEQUENCES THAT CONTROL
12 THE EXPRESSION OF SETS OF GENES IN PROKARYOTIC, ARCHEA AND
13 EUKARYOTIC GENOMES, incorporated herein by reference.

14
15 The present application is an continuation in part of US Patent
16 Application Serial Number 10/227,568 filed August 26, 2002
17 entitled Determination of flanking DNA sequences that control
18 the expression of sets of genes in the Escherichia coli K-12
19 MG1655 complete genome, incorporated herein by reference.

20
21 **Introduction**

22 The connectron structure of a genome determines sets of four DNA
23 sequences (called C1, C2, T1 and T2) of minimum length of 15-
24 bases (C1 and C2 which are in the 3'UTR of a gene, T1 which is
25 on the 5'-side and T2 which is on the 3'-side of a set of
26 genes). Typical genomes have from hundreds to tens of thousands
27 of these tetradic relationships spread throughout the genome.
28 When a gene is transcribed into RNA the C1 and C2 sequences in
29 the 3'UTR find the cognate T1 and T2 double-stranded DNA
30 sequences to form a pair of triple-stranded RNA-DNA-DNA

31 generalized Hoogsteen helices. The genes between T1 and T2 are
32 condensed into 30nm chromatin structure and they are no longer
33 open to promotion and transcription. The lifetime of each
34 connectron is proportional to the length of the shorter of the
35 two generalized Hoogsteen helices. Within a set of genes that
36 have been removed from promotability by the formation of a
37 connectron there may be genes that themselves have the same or
38 different C1/C2 sequences in their 3'UTRs. This inclusion
39 process induces a temporal dynamic because genes that are
40 included in a connectron can no longer produce the source C1/C2
41 RNA sequences to form other connectrons. One of the most
42 obvious instances of this temporal dynamic are the so-called
43 "one-shot" connectrons in which the transcription of a gene
44 produces a C1/C2 sequence pair that forms a connectron that
45 includes the transcribed gene itself thus turning off the
46 further expression of the gene. In general, however, the
47 connectron sources (i.e. the C1/C2 sequences) and the connectron
48 flanking targets (i.e. T1 and the T2 sequences) are in different
49 portions of the genome. The evolutionary configuration of each
50 genome alone determines whether the genes turned off by one
51 connectron are associated with other connectrons.

52 The C1/C2 sequences that are the sources of connectrons can also
53 bind to the DNA double-stranded sequences of other equivalent
54 C1/C2 sequences in the 3'UTR of other genes. Where these trip-
55 stranded RNA-DNA-DNA generalized Hoogsteen helices form, the
56 translation of the DNA into RNA is halted and no additional
57 C1/C2 connectron source sequences are produced. This
58 interference RNA (iRNA) produces an additional temporal dynamic.
59 Once again the lifetime of this iRNA is varies directly with the
60 length of the C1 and C2 sequences. Only the relative lengths of
61 the lifetimes distinguish iRNAs from small temporal RNAs
62 (stRNAs). The iRNA and stRNA modulate the temporal behavior of
63 the connectrons.

64 The third type sequence-determined component that produces a
65 temporal dynamic is the permanent connectron. If all the C1/C2
66 sources of a given connectron can be turned off by the action of
67 other connectrons, then it is called a "transient connectron".
68 If, however, the generation of the C1/C2 source of a connectron
69 is controlled only by promotion of its associated gene then the
70 connectron is described as being "permanent". The gene and its
71 3'UTR are always open to transcription and hence the C1/C2 RNA
72 could be continually produced. Permanent connectrons have a
73 dominant role in the temporal dynamic. Since the permanent
74 connectrons cannot be altered by any subsequent connectron, RNAi
75 or stRNA events, they act to determine in large measure temporal
76 activity of the whole cell. As the documentation of genes for
77 many of the different genomes publically available on the
78 National Center for Biomedical Information (NCBI) server
79 improves, the number of permanent connectrons detected by our
80 basic-methods algorithm is becoming fewer and fewer.

81 An analogy will help to make the roles of the three sequence-
82 determined components clearer. A musical organ is a device with
83 three control components and one notation component. There are
84 the stops that act to connect the tone-producing pipes to the
85 keys on different keyboards. The pedals act to modulate the
86 tones produced by individual key actions at a given time. In an
87 organ the keys on different keyboards are depressed in a variety
88 of sequences to produce the melody. The pedals are depressed in
89 a somewhat slower fashion to produce different harmonies. As a
90 composition moves from one phase to another, the organist will
91 often change the pattern of the stops. The tempo of the
92 composition is mainly determined by the rapid alteration of key
93 depressions on the different keyboards. Unlike a piano or a
94 harpsichord where such an action produces little effect, in
95 organ music a given key can sometimes be held down for a
96 relatively long time. In the same way, a pedal can be depressed
97 for just a short time to produce just the hint of a harmony.
98 The dynamic range of organ music, especially in an ancient

99 cathedral, produces a sense of awe in most minds. The temporal
100 behavior of cell is really very similar and just as full of awe.
101 The connectrons interact with each other to produce most of the
102 rapid changes in gene expression. Sets of genes (where a set
103 can be one gene or many genes) are turned-off and, when the
104 lifetime of the connectron expires, turned-on again. Since the
105 lifetime of a connectron is determined by the length of the
106 minimum intersecting sequences, some connectron lifetimes are
107 very short while others are quite long. The iRNAs and the stRNA
108 produced by gene expression also have lifetimes so they too can
109 act in short-term or long-term fashions. In the same way that
110 the pedals act to modulate the effect of the keys, the iRNAs and
111 stRNAs act to modulate the temporal behavior and interaction of
112 the connectrons. The different keyboards in an organ correspond
113 to the different chromosomes in a genome. Like the stops that
114 determine the major sound forms in an organ, the permanent
115 connectrons (which are most probably driven by alarm signals
116 from outside the cell) determine the major aspects of gene
117 expression behavior. In the same way that certain patterns of
118 stops will be used for toccatas and others for fugues, we can
119 expect to find permanent connectrons associated with cell-cycle,
120 change of energy sources, and even external calls for the cell
121 to commit suicide (i.e. apoptosis). In the organ analogy the
122 music (i.e. the notation component) is separate from the
123 instrument itself. The organist can bring any piece of music to
124 an instrument and play it. Genomes occasionally receive DNA
125 from outside sources. Although it may be stretching the analogy
126 a bit, one might argue that the cell might "play" the new DNA to
127 see if it confers any new evolutionarily advantageous
128 properties. In the basic method patent we showed that some
129 connectrons are controlled by promoters that do not produce an
130 Open Reading Frame (ORF). These ORF-less transcripts do include
131 C1/C2 sequences. As we have processed more prokaryotic, archeal
132 and eukaryotic genomes to determine their connectron structure,
133 the number of short gene-like fragments called pseudo-genes have
134 increased. In the eukaryotic genomes the size of the human

135 genome (i.e. 3.5 billion bases), there is still about 90% of the
136 genomic DNA that is not well characterized. It may be that this
137 is where the "music" of the cell is stored. The utilization of
138 this program may be able to resolve this question.

139 This invention is a program method for the simulation of
140 cellular gene expression behavior by means of the interaction of
141 permanent and transient connectrons along with the iRNAs and the
142 stRNAs.

143

144 **Prior Art**

145

146 The Prior Art disclosed in my above identified Patent
147 Application is incorporated herein by reference.

148

149 **Brief Description of the Objects of the** 150 **Invention**

151

152

153 The object of the invention is to provide a method for using
154 permanent and transient connectrons and/or iRNAs and stRNAs to
155 show how connectrons control the expression of the genes in a
156 cell.

157

158 **Description of the Drawings**

159 The above and other objects, advantages and features of the
160 invention will become more apparent when considered with the
161 following specification and accompanying drawings wherein:

162

163 Figure 1 illustrates that (a) Complex Representation of
164 Connectron Formation. (b) Simplified Representation of
165 Connectron Formation,

166
167 Figure 2 illustrates that using the simplified notation (a) At
168 first Genes c1, c2 and c3 are free to be expressed under
169 ordinary promotional control. (b) Then Gene b2 begins to
170 express thus forming a connectron that turns off the expression
171 of Genes c1, c2 and c3,

172
173 Figure 3 illustrates that (a) Gene a1 begins to express thus
174 forming a connectron that turns off the expression of Genes b1,
175 b2 and b3. (b) As a result, the connectron that turned off the
176 expression of Genes c1, c2 and c3 is eliminated at the end of
177 its lifetime and then Genes c1, c2 and c3 are capable once again
178 of being expressed under promotional control,

179
180 Figure 4 illustrates that (a) If Gene c2 happens to express, it
181 will generate a connectron that controls the expression of Genes
182 a1 and a2. (b) As a result, the connectron formed by Gene a1 is
183 allowed to expire at the end of its lifetime thus making it
184 possible for Genes b1, b2 and b3 to be expressed under ordinary
185 promotional control,

186
187 Figure 5 illustrates that if Gene d1 is only under promotional
188 control, then it will generate a permanent connectron that
189 controls the expression of Genes c1, c2 and c3. The permanent
190 connectron generated by Gene d1 will break the cycle of gene
191 expression control among the "a", "b" and "c" genes,

192
193 Figure 6 illustrates that (a) Gene a1 can exert control over
194 Cycle 1 while Gene b1 can exert control over Cycles 2 and 3.
195 (b) A portion of the C1/C2 of Gene b1 is different from the
196 C1/C2 of Gene a1. When Gene b1 expresses, the iRNA suppresses
197 the expression of Gene a1 thus modulating its control over Cycle
198 1,

199
200 Figure 7 illustrates that (a) Two connectrons that are not in
201 conflict. (b) Gene b1 cannot form a connectron. (c) Gene a1
202 can form a connectron because it includes the smaller Gene b1
203 connectron. This is the "Paper covers rock" rule,
204
205 Figure 8 illustrates that (a) Gene b1 cannot form a connectron.
206 (b) Gene b1 cannot form a connectron. (c) Gene b1 can form a
207 connectron as long as the T2 sequence of the Gene a1 connectron
208 is separated from the T1 sequence of the Gene b1 connectron,
209
210 Figure 9 to 13 details the structure of the computer program
211 that simulates the interaction of connectrons and iRNA,
212
213 Figure 14 is a simulation of *E. coli* using random initial
214 conditions, and
215
216 Figure 15 is a plot of the number of changes in connectron
217 activity during a simulation of *E. coli* using random initial
218 conditions.
219

220 Description of the Invention

221
222
223 The interaction of the connectrons and the iRNAs and stRNAs in
224 the genome of a cell generates a temporal dynamic. Figure 1a
225 shows the complex representation of the formation of a
226 connectron. This representation names the chromosome on which
227 the control gene and the C1/C2 sequences reside, as well as
228 naming the chromosome on which the T1 and T2 sequences and the
229 target genes reside. The simplified representation in figure 1b
230 just shows that the control gene causes the formation of a
231 connectron around the target genes. Figures 2, 3 and 4 describe
232 the gene expression control behavior among three sets of genes -
233 called a, b and c. In figure 2a, at first Genes c1, c2 and c3

234 are free to be expressed under ordinary promotional control. In
235 figure 2b, Gene b2 begins to express thus forming a connectron
236 that turns off the expression for Genes c1, c2 and c3. In
237 figure 3a, Gene a1 begins to express thus forming a connectron
238 that turns off the expression of Genes b1, b2 and b3. The
239 result of this connectron formation is shown in figure 3b. As a
240 result of the Gene b2 being turned off the connectron that
241 turned off the expression of Genes c1, c2 and c3 is eliminated
242 at the end of its lifetime because no more RNA is being
243 generated by the expression of the Gene b2. When this
244 connectron is allowed to expire, then Genes c1, c2 and c3 are
245 capable of being expressed under ordinary promotional control.
246 Now for the sake of this example, let us consider that the newly
247 expressible Gene c2 forms a connectron that turns off the
248 expression of the Genes a1 and a2. This action is shown in
249 figure 4a. As a result of turning off the Genes a1 and a2, the
250 connectron formed by Gene a1 that controls the expression of
251 Genes b1, b2 and b3 is allowed to expire at the end of its
252 lifetime. In this example we have a temporal cycle of gene
253 expression control. A "b" gene turns off the "c" genes. An "a"
254 gene turns off the expression of the "b" genes. A "c" gene
255 turns off the expression of the "a" genes, etc. Once started,
256 this cycle can continue indefinitely. If one of the controlling
257 genes in this cycle is not expressed because of promotional
258 control in the cellular environment, then the cycle of gene
259 expression control will die away.

260

261 Figure 5 shows how a permanent connectron can influence the
262 behavior of the cycle shown in figures 2 through 4. The
263 expression of Gene d1 is only due to events in the cellular
264 environment - not to any other connectron control. When Gene d1
265 expresses, it generates a connectron that turns of Genes c1, c2
266 and c3. With the "c" genes permanently turned off, they cannot
267 be turned off by the expression of Gene b2. Likewise because
268 the "c" genes are turned off permanently by Gene d1, the Gene c2
269 cannot turn off the "a" genes. In this example, the effect of

the expression of the permanent connectron is to shut off the cycle of gene expression control among the "a", "b" and "c" genes.

These examples are VERY simple. Real genomes are much, much more complex. Typical prokaryotic, Archeal and eukaryotic genomes have from 100 to 100,000 connectrons. The utility of the computer method described in this patent application is that it provides an experimental basis for investigating connectron-controlled behavior in naturally occurring and synthetic conditions.

In figure 6 the cycle of gene expression control described in figures 2 to 4 is further simplified. The numbers of genes within a connectron as well as their names have been eliminated. The three-stage cycle of temporal control is now just an abstract pattern. There could, of course, be more stages in the cycle. For the purpose of this example, in figure 6a Gene a1 can exert control over Cycle 1 and Gene b1 can exert control over Cycles 2 and 3. For the purpose of this example, let us assume that the C1/C2 of Gene b1 contains a portion of the C1/C2 of Gene a1, but that Gene b1 also has a unique portion of its C1/C2 that controls Cycles 2 and 3. If Gene a1 expresses first then it just exerts control over Cycle 1 but if Gene b1 expresses first then it exerts control over cycles 2 and 3. In addition because there is common C1/C2 sequence between Genes b1 and a1 then the iRNA of Gene b1 will block the expression of the C1/C2 of Gene a1. In this way Gene b1 can block the control of Cycle 1 by Gene a1. This is a typical way in which iRNA and stRNAs exert control over cellular behavior.

The interactions of the connectrons in a genome form an abstract state machine. The state of the machine is determined by the pattern of gene groups that are turned off. An important component of this program invention is the development of a graphic capable of representing the complexity of each state as

well as presenting a large number of states for visual examination. In figure 13 such a graphic is presented.

The key element in the computer program shown in figures 9 to 12 is the set of rules for how connectrons interact. Figure 7a shows that two connectrons that do not share any sequence elements can both form. This is particularly true if the two connectrons are on different chromosomes. In figure 7b the connectron generated by Gene a1 forms first. When Gene b1 expresses, its C1/C2 RNA cannot form a connectron because the corresponding T1-T2 is inaccessible. Figure 7c shows that although Gene b1 has formed a connectron, the connectron produced by the expression of Gene a1 can also form. There is a children's game called "Paper, Scissor, Rock". In this game "Paper covers Rock", "Scissor cuts Paper" and "Rock breaks Scissor". The application of this rule may be subjective but the physical implementation in DNA is plausible. Further computational experimentation may resolve the utility of the "Paper covers Rock" rule. Figure 8a shows that Gene a1 has formed a connectron first. Therefore the later expression of Gene b1 cannot form a connectron. Figure 8b shows that the expression of Gene a1 has formed a connectron. The C1 produced by the expression of Gene b1 tries to use a portion of the T2 of the Gene a1 connectron. This type of connectron does not have a plausible physical implementation. In figure 8c the two connectrons share a common T2-T1 sequence. In this case the two connectrons can form because there is a plausible physical implementation - although only just.

Figures 9 through 13 detail the structure of the program that simulates the interaction of connectrons. Figure 9 is the general structure of the computer, the program, the data files and the printing operation. Figure 10 shows the process flow of the program. Figures 11 and 12 describe the dominant calculation process in the program. In conjunction with the connectron conflict resolution rules described above, this

process does the basic simulation of connectron and iRNA interaction. Along with knowledge of our basic methods patent application, someone skilled in the art should be able to take this diagram and reproduce the cell simulation behavior. Figure 13 describes the peripheral processes for generating, printing and plotting the cell simulation data that are shown in figures 14 and 15.

Figure 14 shows a simulation of the E. coli genome. Each vertical line is one group of genes. The presence of a vertical line indicates that the group of genes is turned off by some connectron. The horizontal lines at the right of the figure show the percentage of the gene groups turned off. The lower limit (i.e. the leftmost edge) of this graph is 50% of the gene groups turned off. The two other vertical lines are 60% and 70% of the gene groups turned off. Running down the page, this side-graph shows that as the simulation proceeds, between 75% and 85% of the gene groups are turned off. The vertical stripes on the left side of this graph show that the gene groups that are turned off change quite rapidly and dramatically. There are 1,000 simulation states down the whole page. For the first 100 simulation states the lifetimes of the connectrons are randomized and kept small. This corresponds to a heating phase. From simulation states 101 to 200 the lifetimes of the connectrons are increased from zero to a value determined by the length of the shortest match between the (C1 and T1) sequences and the (C2 and T2) sequences. From simulation state 201 to 1,000 the simulation runs in it normal mode. The simulation produces extraordinarily complex behavior. Part of the utility of this invention is that it will enable us to study small and large, as well as simple and complex genomic systems (i.e. cells). By varying the lifetimes of the connectrons as well as the iRNA and stRNAs, it will be possible to produce a large variety of behaviors.

Figure 15 Shows the results of doing a larger scale simulation. The upper curve is the number of connectrons going into and out of existence during a 1,000 state period. The lower curve is rate of change in a 1,000 state period. The cellular simulation program described in this invention is relatively inexpensive to run in terms of computer time. As a basic cellular simulation tool, this invention will become a workhorse for computational experimentation. The rules of interaction between the connectrons, as well as the time constants associated with the various connectrons and iRNAs can be easily changed.

This invention utilizes the capabilities in application serial no. _____ filed contemporaneously herewith and entitled "Determination of interference RNAs (iRNAs) and small temporal RNAs (stRNAs) and their interaction with connectrons in prokaryotic, archea and eukaryotic genomes". The iRNAs and stRNAs play a vital role in determining the simulation of cellular dynamics.

This invention shows that the ideas of connectrons and interference RNA are very powerful. The computation process described in our basic methods patent application generates for a given genomes a number of connectrons. At first one might assume that these connectrons are static entities. This invention demonstrates that connectrons and iRNA do indeed interact with each other in a parallel yet sequential manner. If a connectron once formed stayed in existence forever, then there would be no temporal dynamic. It is precisely because the connectrons and the iRNA constructs have (triple-stranded generalized Hoogsteen helix determined) lifetimes that the whole genome can exhibit responsive and regulatory behavior. Nature seems to have used a large number of very simple relationships (i.e. the expression of one gene turns off the expression of other genes) to produce very complex behavior. Figure 15 shows

413 that the behavior of the *E. coli* genome is indeed very complex.
414 The utility of this invention will hopefully be that many
415 scientists throughout the world can use this tool to understand
416 and explore the regulatory behavior of many different genomes
417 ranging from the simplest bacteria through the ubiquitous (in
418 the sea) Archea to the plants, animals and mammals that form our
419 global biology.

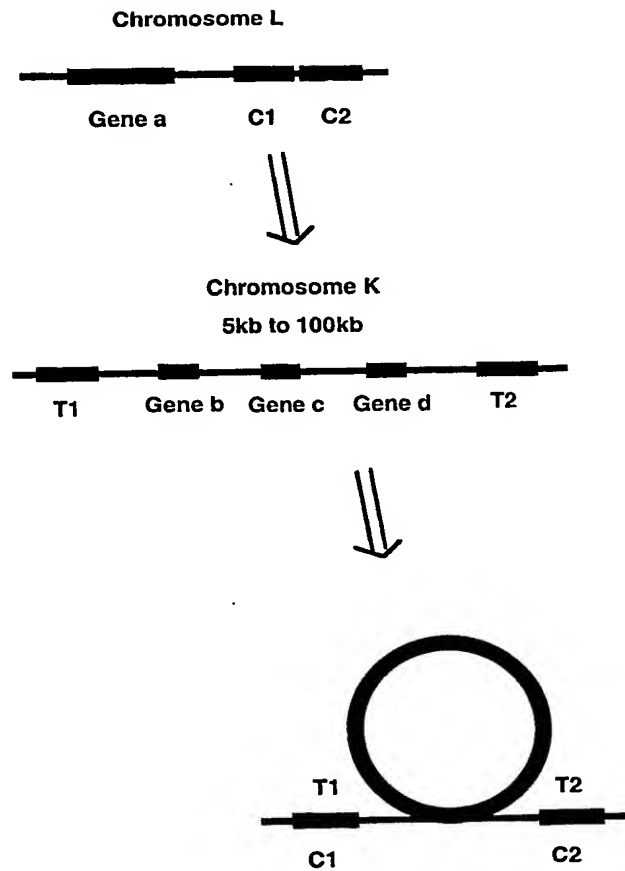

420

Claims

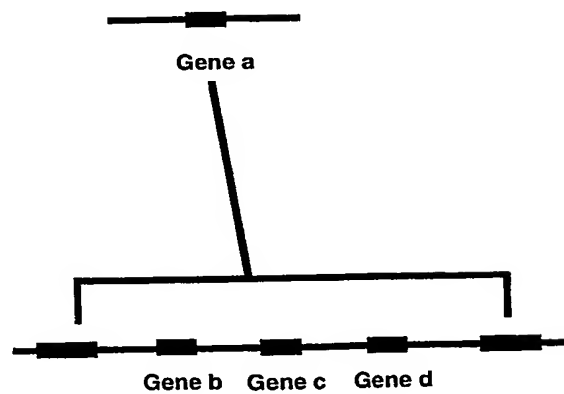

What is claimed is:

1. A method for using permanent and transient connectrons and/or iRNAs and stRNAs to control the expression of the genes in a cell comprising determining, by computer, the interaction of said permanent and transient connectrons and/or iRNAs and stRNAs.

2. A method for using permanent and transient connectrons and/or iRNAs and stRNAs to elucidate the control of the expression of the genes in a cell comprising determining, by computer, the interaction of said permanent and transient connectrons and/or iRNAs and stRNAs.

(a) Complex Representation of Connectron Formation

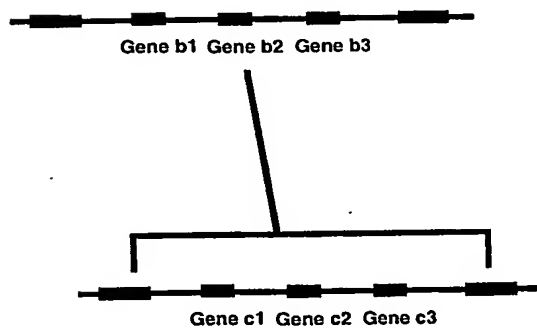

(b) Simplified Representation of Connectron Formation

Figure 1

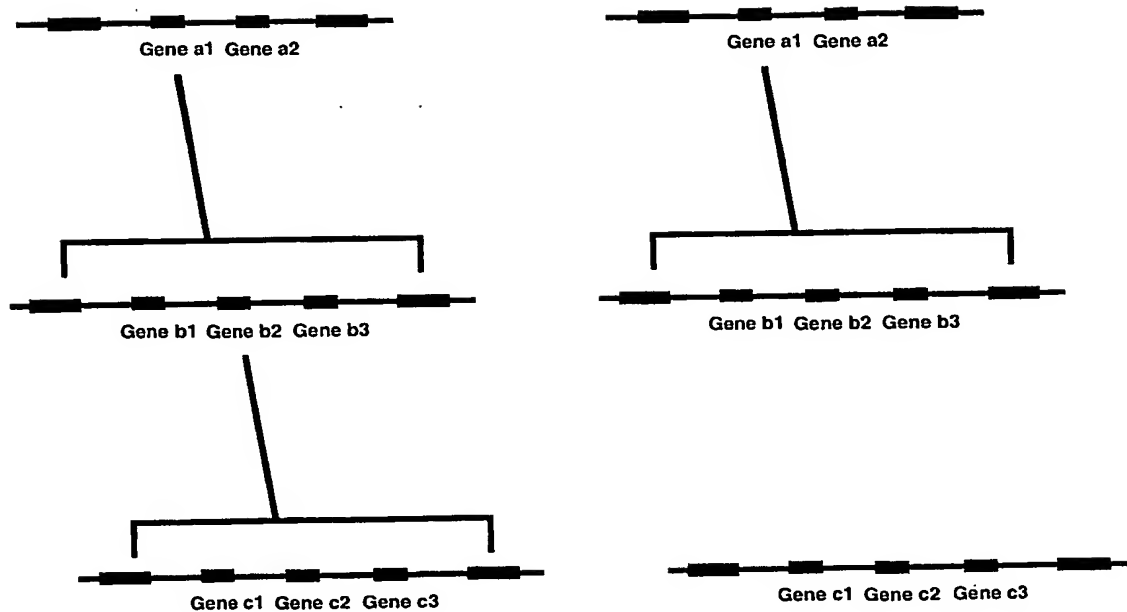

(a) At first Genes c1, c2 and c3 are free to be expressed under ordinary promotional control

(b) Then Gene b2 begins to express forming a connectron that turns off the expression of Genes c1, c2 and c3

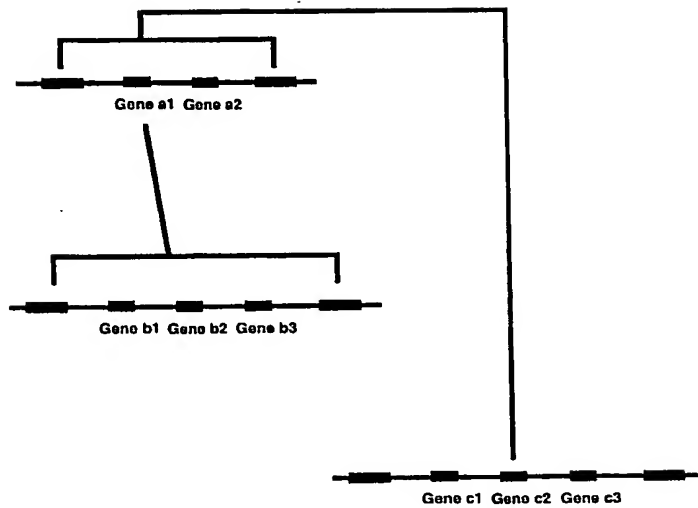

Figure 2

(a) Then gene a1 begins to express forming a connectron that turns off the expression of Genes b1, b2 and b3

(b) As a result the connectron that turned off the expression of Genes c1, c2 and c3 is eliminated at the end of its lifetime and then Genes c1, c2 and c3 are capable once again of being expressed under promotional control

Figure 3

(a) If Gene c2 happens to express, it will generate a connection that controls the expression of Genes a1 and a2

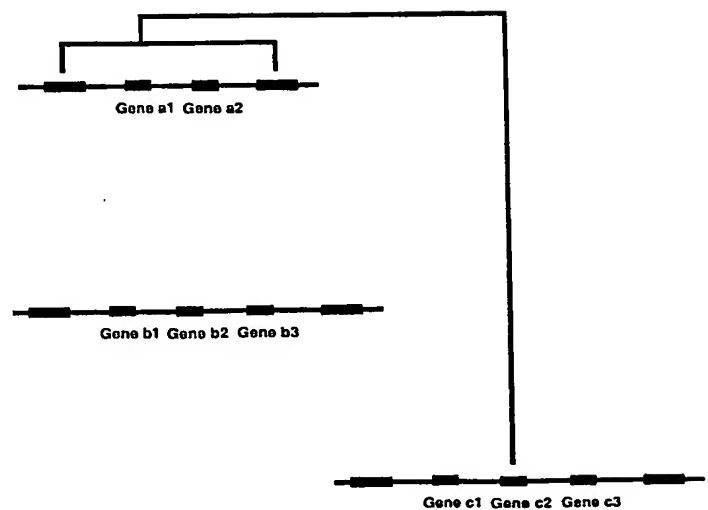

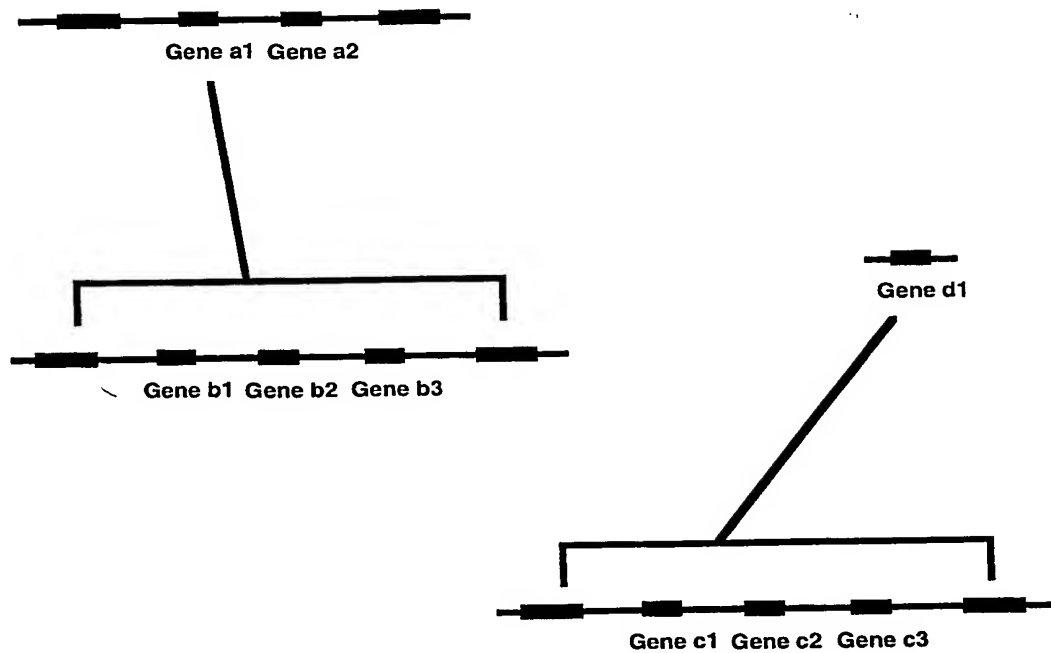

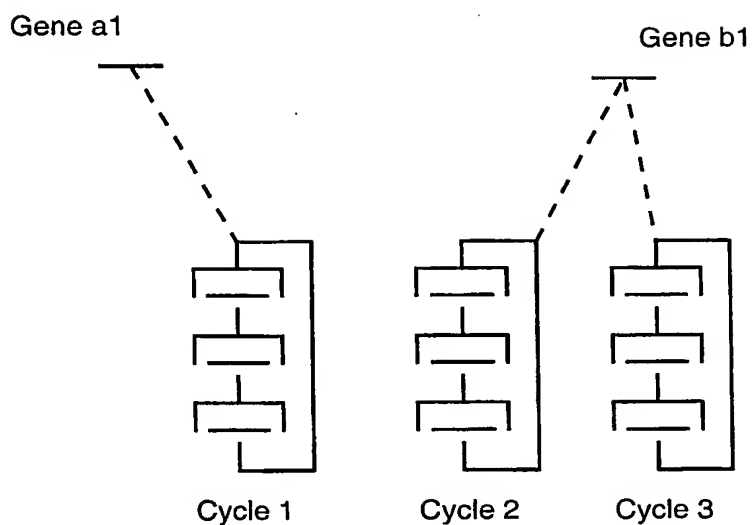

Figure 4

(a) As a result, the connection formed by Gene a1 is allowed to expire at the end of its lifetime thus making it possible for Genes b1, b2 and b3 to be expressed under ordinary promotional control.

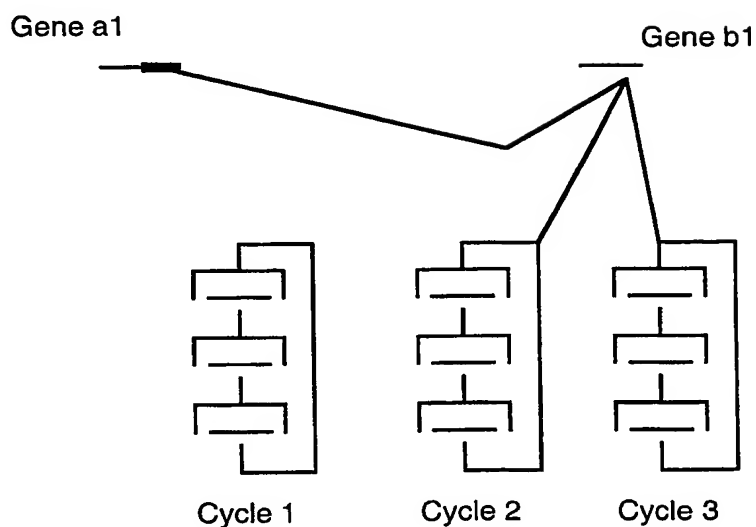

If Gene d1 is only under promotional control, then it will generate a permanent connectron that controls the expression of Genes c1, c2 and c3. The permanent connectron generated by Gene d1 will break the cycle of gene expression control among the a, b and c genes.

Figure 5

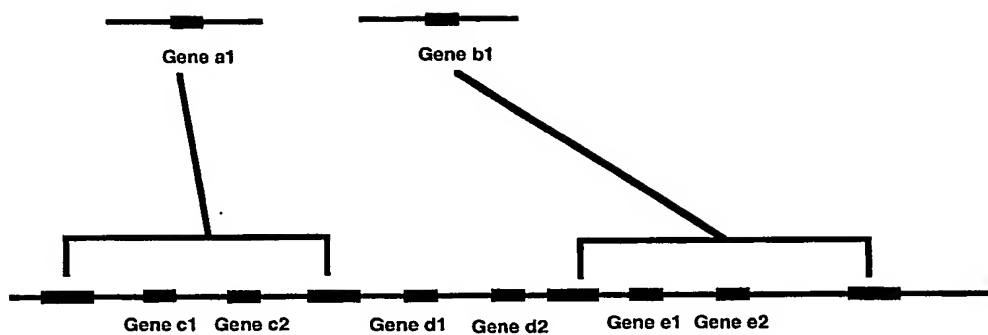

(a) Gene a1 can exert control over Cycle 1 while Gene b1 can exert control over Cycles 2 and 3.

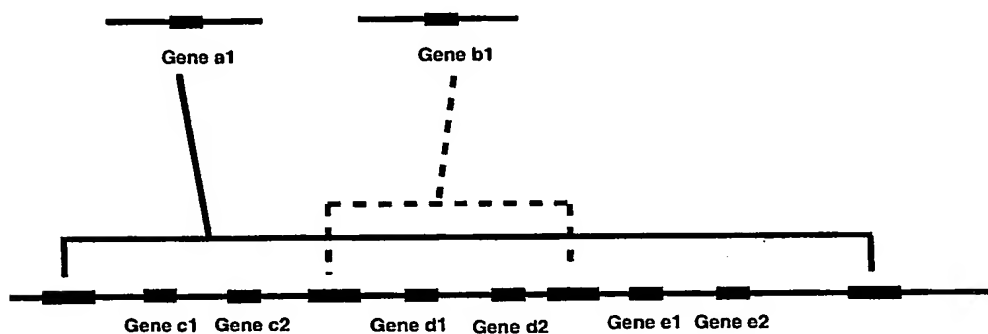

(b) A portion of the C1/C2 of Gene b1 is different from the C1/C1 of Gene a1. When Gene b1 expresses, the iRNA suppresses the expression of Gene a1 thus modulating its control of Cycle 1.

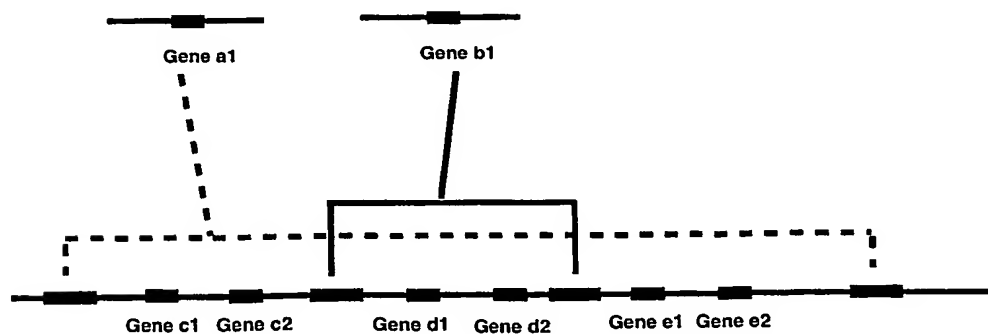

Figure 6

(a) Two connectron that are not in conflict

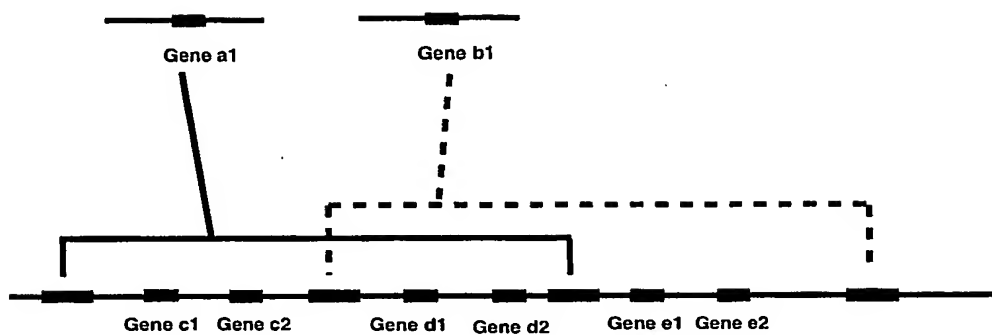

(b) Gene b1 cannot form a connectron

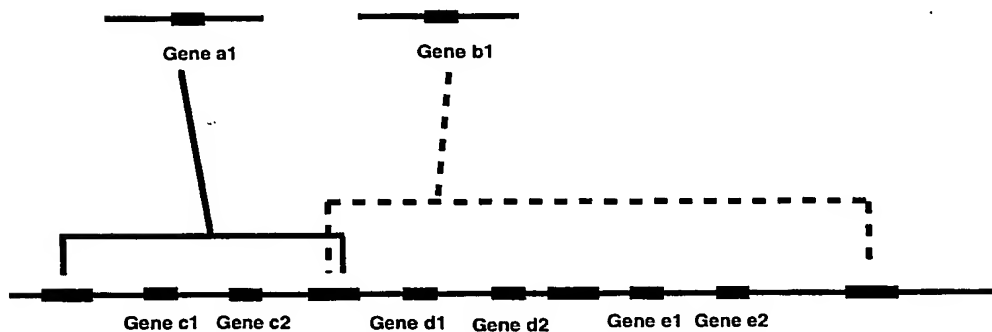

(c) Gene a1 can form a connectron because it includes the smaller Gene b1 connectron. This is the "Paper covers Rock" rule.

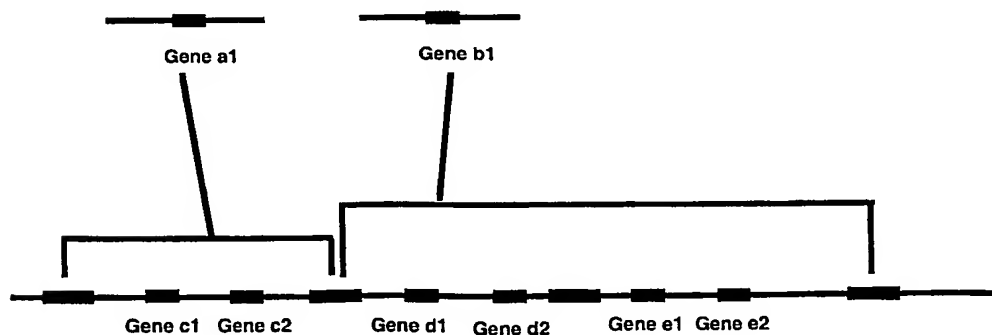

Figure 7

(a) Gene b1 cannot form a connectron

(b) Gene b1 cannot form a connectron

(c) Gene b1 can form a connectron

- (25) Filing Language: English (84) Designated States (*regional*): Eurasian patent (AM, AZ, BY, KG, KZ, MD, RU, TJ, TM), European patent (AT, BE, BG, CH, CY, CZ, DE, DK, EE, ES, FI, FR, GB, GR, HU, IE, IT, LU, MC, NL, PT, SE, SI, SK, TR).
- (26) Publication Language: English
- (30) Priority Data:
60/347,295 14 January 2002 (14.01.2002) US
10/339,666 10 January 2003 (10.01.2003) US Published:
— with international search report
- (71) Applicant: CONNECTRON HOLDING CORPORATION [US/US]; 1712 N. Hartford Street, Arlington, VA 22201 (US). (88) Date of publication of the international search report:
18 December 2003
- (72) Inventor: FELDMANN, Richard, J.; 17800 Mill Creek Drive, Derwood, MD 20855-1019 (US).
For two-letter codes and other abbreviations, refer to the "Guidance Notes on Codes and Abbreviations" appearing at the beginning of each regular issue of the PCT Gazette.

WO 03/060656 A3

(54) Title: SIMULATION OF GENE EXPRESSION CONTROL USING CONNECTRONS.

(57) Abstract: A computer method for the determination of the interaction between transient and permanent connectrons, interference RNA and small temporal RNA.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US03/00022

A. CLASSIFICATION OF SUBJECT MATTER

IPC(7) : G06F 19/00

US CL : 702/20

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 702/20

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)
Please See Continuation Sheet

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	MATTICK, J.S. Non-coding RNAs: the architects of eukaryotic complexity. EMBO Reports, 2001, Vol. 2, No. 11, pages 986-991, especially page 986.	1, 2
X	WO 01/094542 A2(GLOBAL DETERMINANTS, INC.) 13 December 2001 (13.12.2001), page 2.	1, 2

Further documents are listed in the continuation of Box C.

See patent family annex.

* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

Date of the actual completion of the international search

25 April 2003 (25.04.2003)

Date of mailing of the international search report

10 SEP 2003
